Code Critique of AngelAlums

For AAA
By RandomEngineers

Flaw 1

Many of the controller methods that check for conditions (if a user is an alum, if a user can edit, etc.) redirect the user if the conditions are failed. These redirects though do not have a notice or message attached to them explaining why the user has been redirected - it may be helpful to the user if there was a short message explaining the reason for the redirect.

Flaw 2

Why is there a separate update controller? - what is the update model? Why isn't this part of the project data object?

At first glance it seems that having a separate update controller and model introduces extra complexity - why can you not just use the update method in the project controller?

Flaw 3

In some views (e.g. users/show), HTML objects have a lot of styling - why not defined classes and write the styling in the stylesheets?

Flaw 4

There is a chunk of commented code in the project/index view - use GitHub and commits as a way to look at what has been written before.

Additional Notes

The Comment in the new method of project controller is a bit ambiguous - you may want to explicitly define what each of the objects are.

Might want to comment the search controller - at least for me it seemed very complex.

What is the home view - there is a weird view file that does not seem to contain very much?
